Smart Wardrobe — Features & User Guide

Educational reference • Bootcamp M4.3 • October 2026

Document purpose

This document is a self-contained sample product specification for the M4.3 retrieval-augmented generation (RAG) exercise. It describes intended user workflows, not a verification of implemented production features.

1. Product concept

Smart Wardrobe is a personal digital wardrobe concept. Users can organize clothing items, browse their collection, assemble outfits, and receive outfit suggestions based on available wardrobe data.

2. Adding clothing

A user adds an item by uploading a photo and reviewing its details. Relevant fields include item name, category, color, pattern, material, season, and occasion. AI-assisted classification can propose these values, but users should be able to correct incorrect suggestions.

3. Wardrobe categories

The sample taxonomy uses six top-level categories: Tops, Bottoms, Dresses, Outerwear, Shoes, and Accessories. These are example categories for the exercise and may be refined during product development.

4. Outfit creation

A user can select multiple saved garments to create an outfit. The planned outfit builder should support manually assembled combinations and AI-assisted recommendations. A saved outfit includes a title and references to its clothing items.

5. Personal style preferences

The proposed onboarding collects preferred styles, such as Minimalist, Classic, Casual, and Elegant. Preferences should influence outfit suggestions, while remaining editable later.

6. Travel packing concept

A future packing assistant could suggest clothing for a trip based on destination, trip duration, expected weather, and planned activities. Weather data would require an external source.

7. User corrections and trust

Automatic clothing recognition may misclassify category, color, pattern, or season. Users should review AI-generated labels before relying on them. Suggestions should use saved wardrobe items rather than claim the user owns clothing that was never uploaded.

8. Virtual try-on

Virtual try-on is a planned advanced feature, not a capability established by this sample document. It would let users preview garments on a person using a specialized image model or provider.

9. Example user journey

A user uploads a black blazer, corrects the proposed category to Outerwear, labels it as suitable for work, combines it with saved trousers and shoes, and saves the combination as 'Office Dinner'.
